

# Carrying out experiments with genetic algorithms

Example using the *Knapsack* problem

# 1 – Creating the project executable

- Steps:

- Access the command line and position yourself in the python folder:

For example: `cd C:\Users\admin\AppData\Local\Programs\Python\Python311\Scripts\`

- Install *pyinstaller* using pip:

`pip install pyinstaller`

- Position yourself in the project folder on which you want to create the executable:

`cd folder_path`

- Run the following command to create the executable:

`C:\Users\admin\AppData\Local\Programs\Python\Python311\Scripts\pyinstaller --onefile main.py`

Note: The main.exe file will be created in your project's dist folder

It may be necessary to previously install the numpy and matplotlib libraries using pip:

*`pip install numpy / pip install matplotlib`*

It may be necessary to incorporate the *matplotlib* library using:

*`pyinstaller --hidden-import matplotlib.backends.backend_tkagg --onefile main.py`*

# 2 – Creating the folder structure for the experiments

*Tests*

*Dataset1*

*GeneralTests*

*Tournament*

*Population*

*Recombination*

*Mutation*

*Dataset2*

*GeneralTests*

*Tournament*

*Population*

*Recombination*

*Mutation*

...

## **Files to place inside each subfolder:**

(the .exe file is placed inside each subfolder, so that each type of experiment is saved in different excel files)

*data\_set\_1.txt*

*main.exe*

*config.txt*

*data\_set\_2.txt*

*main.exe*

*config.txt*

...

# 3 – Performing experiments

Consider the project developed in class for the Knapsack problem (main.exe executable file)

1 – Start by carrying out preliminary analyzes on each dataset, in order to find out the values of the parameters that are best suited to solving the problem. In this analysis, it should be possible to identify the appropriate number of generations (population size and number of generations depend on the complexity of the optimization problem and must be determined experimentally for each dataset)

2 – Perform (automated) experiments with the variation slightly above/below the values found to determine the best combination of parameters. Use between 30 to 50 runs for each combination of parameters

3 – Carry out (automated) experiments that vary the various GA parameters, to produce graphs that show the influence of their values on the fitness average:

- Population vs generations
- Tournament size
- Recombination methods and their probabilities
- Mutation methods and their probabilities

# 3.1 – General tests for each dataset

- After preliminary analyzes of the dataset, it is necessary to define the config file that will be used by the application to carry out multiple tests with various combinations of parameters. This file must be placed inside the GeneralTests folder of Dataset1
- In this example (config file shown on the right) 50 runs will be performed for each parameter combination, for Dataset1
- In total this example will allow 16200 experiments to be carried out (324 parameter combinations \* 50 runs)
- The results of these experiments are saved in 3 files:
  - *statistic\_average\_fitness*
  - *statistic\_best\_per\_experiment*
  - *statistic\_best\_per\_experiment\_fitness*
- The file that should be used for analysis of the best combination of parameters should be the file *statistic\_average\_fitness*

```
Runs: 50

Population_size: 50, 100, 200

Max_generations: 50

# -----

Selection: tournament

Tournament_size: 2, 4, 6, 8

# -----

Recombination: one_cut, two_cuts, uniform

Recombination_probability: 0.6, 0.7, 0.8

# -----

Mutation: binary

Mutation_probability: 0.01, 0.025, 0.03

# -----

Probability_of_1s: 0.05

Fitness_type: 0

# -----

Problem_file: ./data_set_1.txt

# -----

Statistic: BestIndividual
Statistic: BestAverage
```

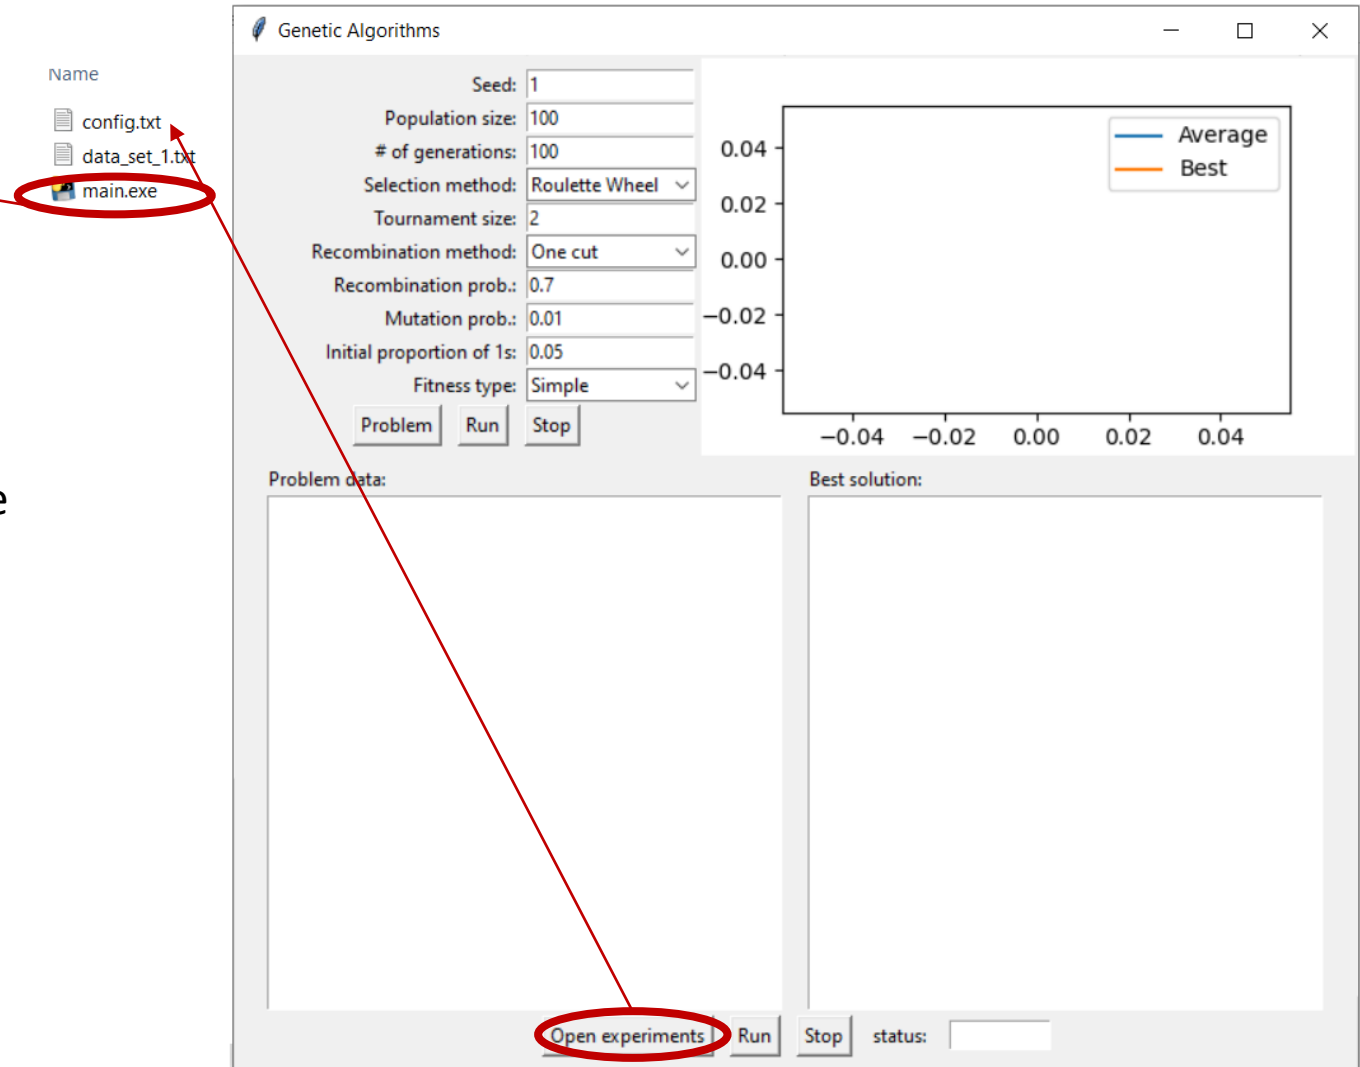

## 3.1 – General tests for each dataset (cont.)

1 – Run the .exe file

2 – Click on *Open experiments* and select the *config* file

3 – Click on *Run*

- *status: running* will be displayed right after the start of the experiments
- Upon completion of the experiments, the *status: finished* will be displayed
- The files generated by the experiments must not be opened until the program has finished the experiments (if you want to consult their contents, copy the files to a temporary folder)

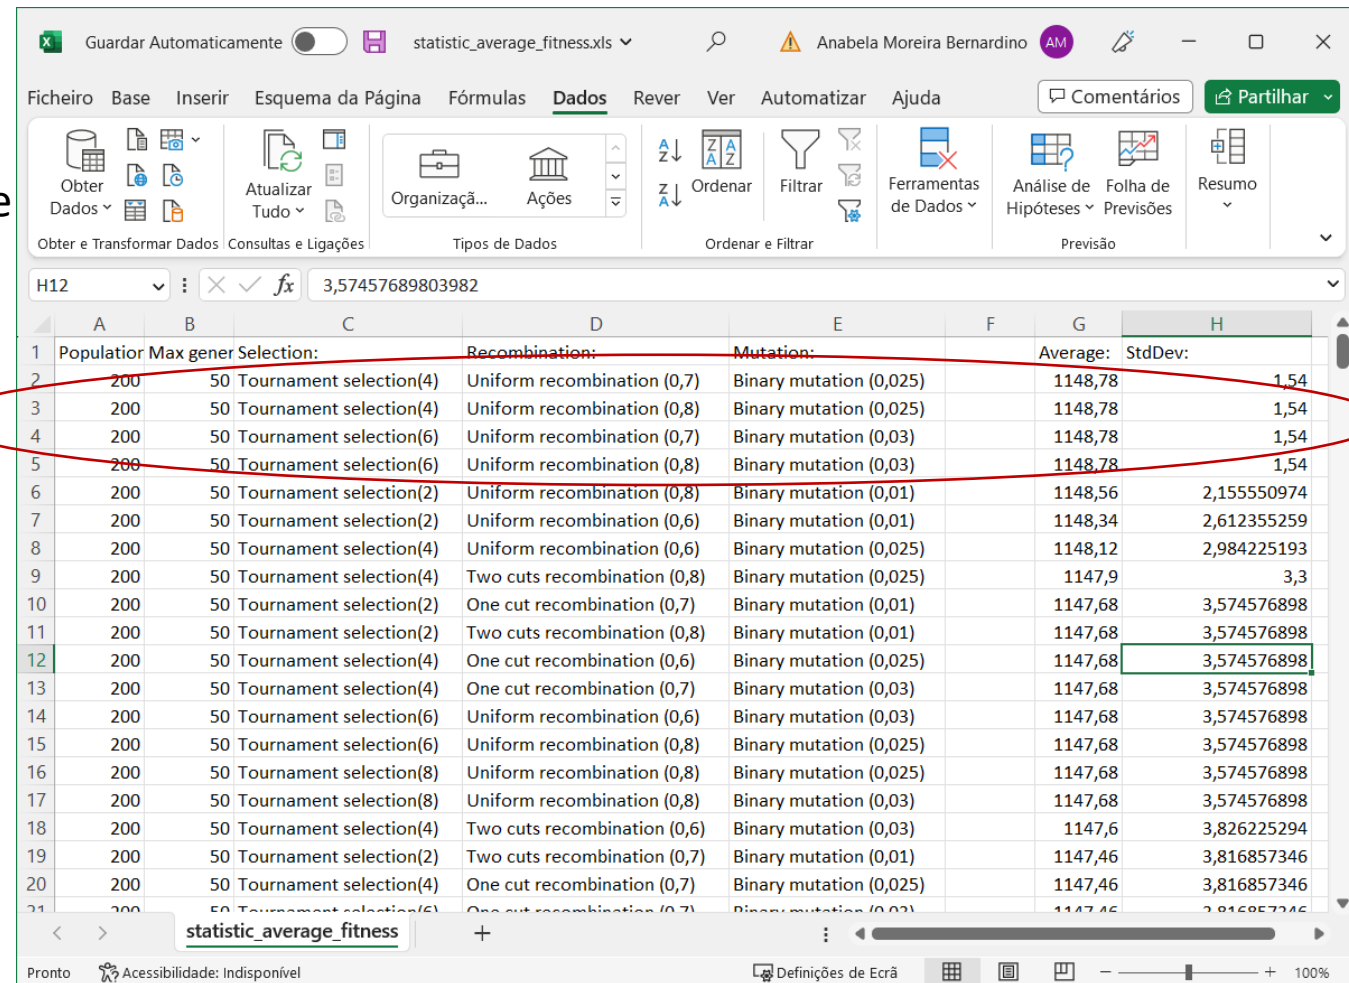

# 3.1 – General tests for each dataset (cont.)

1 – Open the *statistic\_average\_fitness* file

2 – Verify that the data in the Average column appears right-aligned. If they are not aligned to the right, it is necessary to change the formatting of the numbers in the Excel options, or simply select the column data and replace '.' with ','

3 – Sort the data in descending order of the Average column (in the Knapsack problem the best combination of parameters is the one with the highest average fitness)

As can be seen, the best result obtained was for the combination of parameters *population 200, tournament 4/6, uniform recombination 0.7/0.8 and binary mutation 0.025/0.03*

	A	B	C	D	E	F	G	H
	Population	Max gener	Selection:	Recombination:	Mutation:		Average:	StdDev:
2	200	50	Tournament selection(4)	Uniform recombination (0,7)	Binary mutation (0,025)		1148,78	1,54

15	200	50	Tournament selection(6)	Uniform recombination (0,8)	Binary mutation (0,025)		1147,68	3,574576898
16	200	50	Tournament selection(8)	Uniform recombination (0,8)	Binary mutation (0,025)		1147,68	3,574576898
17	200	50	Tournament selection(8)	Uniform recombination (0,8)	Binary mutation (0,03)		1147,68	3,574576898
18	200	50	Tournament selection(4)	Two cuts recombination (0,6)	Binary mutation (0,03)		1147,6	3,826225294
19	200	50	Tournament selection(2)	Two cuts recombination (0,7)	Binary mutation (0,01)		1147,46	3,816857346
20	200	50	Tournament selection(4)	One cut recombination (0,7)	Binary mutation (0,025)		1147,46	3,816857346
21	200	50	Tournament selection(6)	One cut recombination (0,7)	Binary mutation (0,03)		1147,46	3,816857346

## 3.2 – Population size

- The number of generations is related to the size of the population and the computational time available for running the algorithm
- The user must choose between using a small population with many generations or a larger population with fewer generations
- Since in the general tests the best result was obtained with a population of 200 individuals and 50 generations, we will test various population sizes, to confirm whether this is indeed the best value:
  - Pop 50 → 120 gerações
  - Pop 100 → 60 gerações
  - Pop 200 → 30 gerações
  - Pop 400 → 15 gerações
  - Pop 500 → 12 gerações
- The config file shown on the right makes combinations of all population types, with all maximum numbers of generations. In the remaining parameters, the best combination obtained in the general tests of Dataset1 is placed. The graph to be created should contain only 5 bars, and the remaining data must be deleted

```
Runs: 50

Population_size: 50, 100, 200, 400, 500

Max_generations: 12, 15, 30, 60, 120

#-----

Selection: tournament

Tournament_size: 4

#-----

Recombination: uniform

Recombination_probability: 0.8

#-----

Mutation: binary

Mutation_probability: 0.025

#-----

Probability_of_1s: 0.05

Fitness_type: 0

#-----

Problem_file: ./data_set_1.txt

#-----

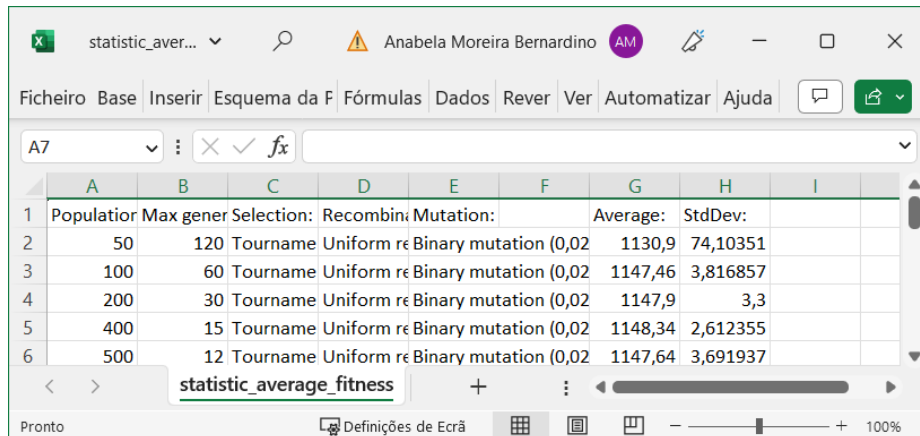

Statistic: BestIndividual
Statistic: BestAverage
```

## 3.2 – Population size (cont.)

- After completing the tests, you should open the *statistic\_average\_fitness* file

- Delete extra lines:

statistic\_average\_fitness

Pronto

## 3.2 – Population size (cont.)

- Creating the chart automatically:
  - Convert the generation and population columns to text (in the example below, the text *pop* was added to the population column and *ger* to the generation column)
  - Convert the average fitness column to a number (if the numbers do not appear aligned to the right, it is necessary to change the formatting of the numbers in the Excel options, or simply select the column data and replace '.' with ',')
  - Select the population size, number of generations and average fitness data columns and create a column chart
  - Add titles on the vertical and horizontal axes and add a title to the chart
  - Add data labels to chart columns

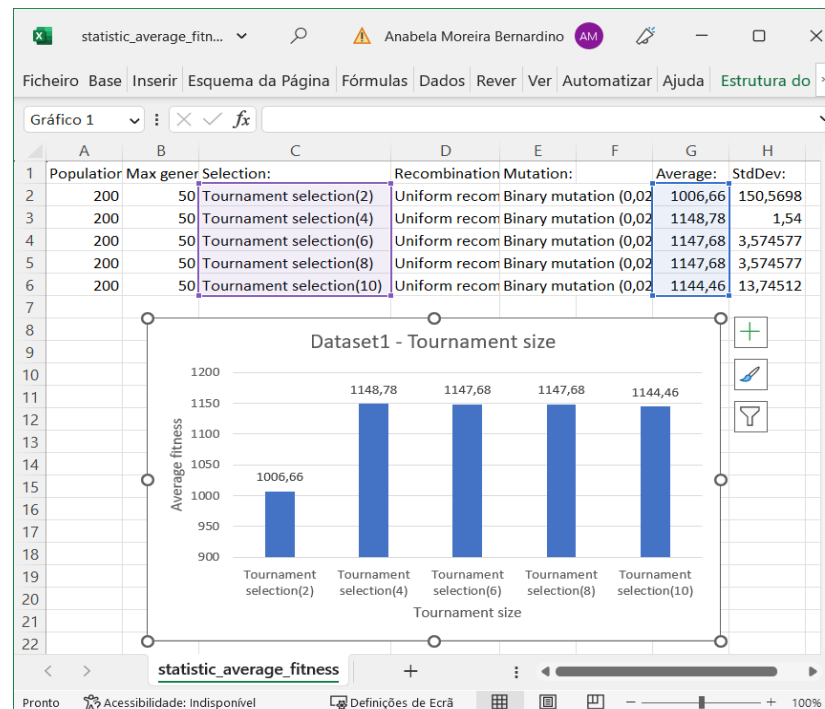

As can be seen from the chart, the populations that show the best results are the 200 and 400

## 3.3 – Tournament size

- The config file shown on the right contains the tournament size variation
- In the remaining parameters, the best combination obtained in the general tests is placed
- After carrying out the tests, open the *statistic\_average\_fitness* file and create a chart identical to the one shown below (check before creating the chart that the data in the Average column is aligned to the right)

As can be seen in the graph, the best result was obtained for tournament 4

Runs: 50

Population\_size: 200

Max\_generations: 50

#-----

Selection: tournament

Tournament\_size: 2, 4, 6, 8, 10

#-----

Recombination: uniform

Recombination\_probability: 0.8

#-----

Mutation: binary

Mutation\_probability: 0.025

#-----

Probability\_of\_1s: 0.05

Fitness\_type: 0

#-----

Problem\_file: ./data\_set\_1.txt

#-----

Statistic: BestIndividual

Statistic: BestAverage

## 3.4 – Recombination

- The config file shown on the right contains the variation of the various recombination methods with the various recombination probabilities
- In the remaining parameters, the best combination obtained in the general tests is placed
- After carrying out the tests, the *statistic\_average\_fitness* file should be opened

	A	B	C	D	E	F	G	H	I

# 3.4 – Recombination (cont.)

- Check that the data in the Average column is aligned to the right (in the example below, the '.' was replaced by ',' since the data in this column was recognized as a number)
- Select data from Recombination and Average columns and create a bar chart
- Increase the size of the chart vertically so that all probabilities from 0.1 to 0.9 appear

## 3.4 – Recombination (cont.)

- After creating the chart, add titles on the vertical and horizontal axes and add a title to the chart
- Add data labels to chart columns

Observing the chart, we can conclude:

- The best result is obtained for uniform recombination, probabilities 0.7, 0.8 and 0.9
- The best probabilities for two-cut recombination are 0.8 and 0.9 and for one-cut recombination is 0.6

## 3.5 – Mutation

- In the Knapsack project there was only one mutation implemented, so it was only necessary to vary the various mutation probabilities
- In the project to be developed at the AI course, a config file identical to the one created for recombination should be created and a chart showing the influence of the various probabilities for each mutation method should be created

# Performing experiments for the course project

Considerations for automated experiments:

- Use between 30 to 50 runs for each combination of parameters
- Save the config files created for each experiment and the files resulting from the experiments (which must be delivered together with the project code)
- After carrying out all the experiments, delete all .exe files from the test folders

The project report should include:

- Information on the best combination of parameters for each dataset
- The best result obtained (best fitness) and the fitness average (of the  $x$  runs performed)
- A chart with the results obtained for each combination of parameters for each dataset (tournament, population vs generations, recombinations, mutations)
- All results presented in tables and charts must be properly described in the text of the report

**Have a nice time performing experiments 😊**
